Abstract: 

Na\(^+\)-K\(^+\)-ATPase is a membrane bound enzyme responsible for the transport of ions through the membrane and immediate release of energy. This enzyme is known to be an early target for oxygen radical induced damage to intact cell. Exposure of *C. punctatus* to subacute concentrations of lindane for 96 h caused significant reduction in the activities of Na\(^+\)-K\(^+\)-ATPase in all the tissues of the fish tested; brain being maximally affected and the heart being least affected organ at the highest concentration of lindane (0.1 mg/L). The effect of pesticide was concentration dependent. The percent decrease in the activity of Na\(^+\)-K\(^+\)-ATPase in brain, gills, heart, kidney, liver and muscle was found to be 36.7, 23.4, 19.2, 29, 22.9 and 29.7, respectively. The order of level of enzyme activity recorded was as following: liver > gills > kidney > brain > muscle > heart in the control.

Keywords: Lindane; Na-K-ATPase; organs

1. Introduction

The aquatic ecosystem is an open system exposed to all different kind of pollutants, toxicants, surfactants thus polluting the aquatic environment. Their direct discharge without any pre-treatment either leads to large scale destruction of aquatic life or accumulation in water, soil/bioaccumulation in biotic aquata. Though, the pollutants could be biodegradable or non-biodegradable, these pollutants sometimes, decrease the rate of decay of biodegradables. Thus, the increase in the contaminants may allow their environmental persistence for longer period. Excessive use of nitrate and phosphate fertilizers may lead to eutrophication, thereby reducing the amount of oxygen in the aquatic biota and increasing the biological oxygen demand of that water for prolonged period. Industrial smokes, burning of woods, petroleum, and vehicles fumes all gave rise to gases like sulphur dioxide, nitrogen oxides, and carbon dioxide; lead, and the particulate matters, all have caused serious harm to the environment and humans [1–3]. Reports on the increased levels of heavy metals and pesticides and their effects on oxidative stress have been exhaustively documented [4–8]. Many bacteria like *Vibrio anguillarum, Aeromonas, Flavobacterium, Pseudomonas, Serratia, and Yersina,* etc. have been shown to grow in water, which has less oxygen, increased organic matter, and unsuitable pH for the aquatic life.

The presence of organic matter may be due to leakage from septic tanks or contamination by domestic sewage [9]. Aquatic life may suffer from diseases like fin rot, papilloma, hyper-neoplasia, and gill diseases etc. Gills are the main respiratory organs of fish; it regulates ion concentration and osmotic balance for survival in unfavorable concentrations [10]. Decrease in function of gills has been reported when exposed to pH of water less or more than 7 [11]. Lindane is an organochlorine,
hydrophobic, and highly persistent pesticide. Due to its lipophilic nature, it gets easily bioaccumulated in aquatic organisms. Lindane is strongly adsorbed on soils that contain a large amount of organic matter. It can move downward by capillary action through the soil with water from rainfall or artificial irrigation. In the UV light it undergoes rapid dichlorination or degradation to form pentachloro cyclohexenes and tetrachlorocyclohexenes. The fish are able to bioaccumulate due to direct exposure to chemicals in water, and ingestion of contaminated food or preys [12]. Their accumulation in low concentration in aquatic animals generate warning signals about the environment. Ultimately in long run when these fish are eaten by humans or animals, the pesticide residues accumulate in different organs of the exposed living systems and hence may pose serious health problems [13]. The pesticide and its residues are known to get strongly adsorbed on clays and sediments of surface water where several fish population reside for feeding.

Sodium Potassium ATPases (Na⁺-K⁺-ATPase, EC 3.6. 3.9) is a membrane bound sulfhydryl containing oligomeric enzyme whose function is critical for the maintenance of cell viability. It works as an electrogenic P-type pump involved in monovalent ion transport across membranes utilizing energy of ATP hydrolysis. It pumps 3 sodium outside (extracellular) and 2 potassium inside the cell membrane (intracellular) for 1 ATP. The concentration gradient created due to ions transport across the membranes help in other secondary transports [14,15]. This pump has many diverse functions like contractions, signalling, homeostasis (osmoregulation), and cell-cell adhesions [16,17]. It also governs many physiological processes like reabsorption, filtration, pH, electrolytes osmotic regulation by kidneys [18], sperm motility [19], and action potential in neurons [20–23]. This pump consists of 3 subunits α, β and FXYD. The α subunit is for ion transport (catalytic) and is under influence of β (auxiliary) and FXYD (tissue specific) subunit [24]. The β2 subunit of Na⁺-K⁺-ATPase is responsible for regulation of egg development in Aedes aegypti, the causative organism of many vectors borne diseases like yellow fever, zika, dengue, chicken guinea. The reduced expression of mRNA of β2 Na⁺-K⁺-ATPase in the knockdown mice showed less egg formation, which directly reduced their population and so less spread of disease [25]. In humans, decreased heart functions or heart failures have been reported due to decrease in its activity [26]. In plants, it helps in nutrient uptake, root development, stomatal regulation, and response to environmental stresses. It helps plants to maintain proper ion balance, participate in nutrient absorption, and regulate turgor pressure in cell. In the environment, it acts as marker for organisms facing challenges such as varying salinity, ion concentrations, or osmotic stress. In the present study, the effect of subacute concentrations of lindane (0.025, 0.05, 0.1 mg/L) on the activity of Na⁺-K⁺-ATPase was assessed in order to evaluate the perturbations in the transport of ions in different fish tissues exposed for 96 h.

2. Materials and methods

2.1. Experimental design and exposure to lindane

The healthy and active fish of 30–40 gm with no signs of any diseases or external injury were equally distributed in four aquaria of 1 × 1 ft. The subacute concentrations
of lindane (0.025, 0.05, 0.1 mg/L) prepared in acetone were used for the exposure of *C. punctatus* for 96 h. In control group, equal volume of acetone was added. All aquaria were constantly aerated during the period of exposure by aerator and the fish were fed properly. The water of all 4 aquaria was changed in 24 h and replenished with fresh lindane.

2.2. Preparation of cell free extracts and biochemical assays

1) Protein determination: The quantitative estimation of total protein in various tissue extracts and solutions were done according to the known procedure [27]. The samples were homogenized 10% (w/v) in 0.05 m sodium phosphate buffer, pH 7.4 and centrifuged at 10,000 rpm for 10 min in cold (4 °C) condition. The supernatants were collected in labelled vials and volume was noted. Determination of protein was done using Folin-Ciocalteau reagent. The bovine serum albumin (BSA) was used as a standard. A blank was prepared, which contained all reagents but no protein. The intensity of blue color was measured colorimetrically at 620 nm.

2) Assay of Na⁺-K⁺-ATPase activity: The Na⁺-K⁺-ATPase activity was determined as inorganic phosphorus (Pi) production using the method of Svobaca and Mossinger [28] and Fiske and Subbarow [29]. The reaction mixture is given in Table 1. All reagents were obtained from Sigma Chemical Company, U.S.A. The pesticide used in the experiments was from Rallis India limited. The double distilled water was used for all biochemical experiments.

2.3. Statistical analysis

The values were presented as means ± standard error of mean (SEM) of observed data of three to five replicates. Graph pad prism version 3.0 (GraphPad Prism Software Inc., San Diego, CA, USA) was used to analysis the data. Results obtained from treated and control fish were compared using Turkeys H test.

3. Results and discussion

Effect of lindane on the activity of Na⁺-K⁺-ATPase in different organs of lindane exposed fish

The data demonstrated highest activity of Na⁺-K⁺-ATPase to be present in liver (41.67 ± 0.35 units/mg protein) and lowest in heart (16.73 ± 0.11 units/mg protein) of the control fish. The activities of Na⁺-K⁺-ATPase in other fish tissues such as gills, kidney, brain and muscle were recorded as 33.78 ± 0.23, 32.87 ± 0.19, 30.29 ± 0.07 and 21.29 ± 0.09 units/mg protein, respectively. The order of level of enzyme activity recorded in the control fish tissues was as following: liver > gills > kidney > brain > muscle > heart (Table 2, Figure 1).

Values are represented as µm of Pi released/h/mg wet weight of tissue. Each value represents the mean ± SEM of ten different observations. Values in parenthesis are percent change over control. The (−) sign represents decrease over control. h represents time in hour. SEM = standard error of mean.
Figure 1. Lindane exposure at different concentrations (0, 0.025, 0.05, 0.1 ppm) on the specific activity of Na\(^+\)-K\(^+\)-ATPase (units/mg protein) in different tissues of *C. punctatus* exposed for 96 h.

From the Turkeys HSD test all pairwise comparisons between different concentrations (0.025, 0.05, 0.1 mg/L) and control (0 mg/L) were statistically significant with \( p < 0.05 \). This indicates that there are significant differences in the mean values between the control and each of the concentrations, as well as between the different concentrations themselves for organs brain, muscle and liver. The non-significant differences were observed in the gills and kidney with 0.1 vs. 0.05 mg/L and heart 0.05 vs. 0.025 mg/L (Table 3).

S = Significant, NS = Not significant.

The treatment of the fish with three subacute concentrations of lindane displayed marked decrease in the activity of Na\(^+\)-K\(^+\)-ATPase in all the tissues tested i.e. brain being maximally affected at all of these concentrations. At lowest concentration of lindane (0.025 mg/L), the fish tissues such as gills, kidney and muscle showed same level of percent inhibition (about 9%–10%) in the enzyme activity (Table 2).

At the highest concentration of the pesticide (0.1 mg/L), the brain of the fish exhibited maximum decrease by 37% in the enzyme activity and the heart indicated minimum decrease by 19% after 96 h of treatment duration. The decrease in the
enzyme activity was in concentration dependent manner. The percent decrease in the activity of Na\(^+\)-K\(^+\)-ATPase in brain, gills, heart, kidney, liver and muscle was found to be 36.7, 23.4, 19.2, 29, 22.9 and 29.7, respectively. The data indicated that the gills and liver were affected by lindane to similar level showing about 23% decrease in enzyme activity. Further, the kidney and muscle displayed almost same level of enzyme inhibition to about 29% when the fish was treated with lindane at 0.1 mg/L concentration for 96h. The extent of inhibition in the enzyme activity from these fish tissues treated with the highest pesticide concentration (0.1 mg/L) was found in the following order: brain > muscle = kidney > gills = liver > heart (Table 2).

This enzyme is known to be an early target for oxygen radical induced damage to intact cell [30,31]. Sharma observed significant reduction of liver ATPase activity in C. gaucha upon en SDSulphan exposure [32]. Oruc et al. reported reduction of liver activity in Tillapia zilli and O. Niloticus and suggested that increased lipid peroxidation disturbed the anatomical integrity of the biomembrane and diminished its fluidity leading to inhibition of activities of several membrane bound enzymes including Na\(^+\)-K\(^+\)-ATPase [33]. Very recently, cypermethrin at lethal (5.03 µg/L) and sublethal (1.02 µg/L) concentrations has been shown to cause significant alterations in gills, liver and muscle of the fish Cirrhinus mrigala [34].

Similar observations have been reported in C. punctatus exposed to pyrethroids [35], Clarias gariepinus juvenile exposed to oxadiazon [35]. Increased activity in gills of silver cat fish (Rhamdia quelen) was reported in water pH 9.0 and no significant change in kidney [36]. In hypotonic environment, kidneys of fish species excrete more dilute urine to maintain homeostasis [37] and in hypertonic they suffer from dehydration and so they drink more sea water excreting out extra salts [38,39]. At lethal concentration, the insecticide caused increased in enzyme activity whereas at sublethal concentration the enzyme activity decreased [40]. Maiti exposed the fish Clarius batrachus to 5.69 mg/L and 11.38 mg/L of chromium (lll) for 96h and reported decrease in activity in brain [41–45]. This inactivity can lead to diverse alterations in the neurons such as partial membrane depolarization, Ca\(^{2+}\) influx, altered neurotransmitter release and even apoptosis and all can be co-related to functional deficits in the brain [46].

4. Conclusions

The significance of sodium-potassium ATPase (Na\(^+\)-K\(^+\)-ATPase) in the environment is its role played in maintaining cellular homeostasis both in plants and animals. It contributes to the adaptability and survival of organisms in diverse environmental conditions and serves as a sensitive indicator of environmental stress and toxicity. The exposure of the fish to varying subacute concentrations of lindane have caused significant perturbations in the activity of this enzyme in different organs of the fish tested. The results may serve as indicator of pesticide contamination in water and better management of pesticide application in agricultural practices to secure environmental health.
